KANSAS POPULATION PROJECTIONS

1985-2020

by

Helga Upmeier, Ph.D.  
Research Associate

These projections were prepared at the request of the Kansas Legislative Educational Planning Committee and the Legislative Research Department to facilitate educational planning in the state, and for research purposes. They are based on the 1980 U.S. Census data and should be perceived, with extreme caution, as broad indicators of future population levels if recent and current trends continue.

Anthony L. Redwood, Executive Director

January 1989

Report No. 158

## PREFACE

The preparation of the Kansas population projections was funded by the State of Kansas at the request of the Kansas Legislative Planning Committee. The Bureau of Business Research at the University of Nebraska-Lincoln provided the initial projection model which has been modified by the Institute for Public Policy and Business Research for Kansas.

The projections are presented by age breakdown for the state and all counties. However, projections by sex breakdown are available for each county on microcomputer diskettes. Furthermore, state and county-level projections can be provided for individual years as an interpolation of the five-year time intervals published in this report.

The author gratefully acknowledges the direction of this project by Dr. Anthony Redwood, who gave his expert advice on demographic issues. In particular, thanks are due to Dr. Larry Hoyle who provided his time and knowledge for the programming and technical assistance.

## 0. EXECUTIVE SUMMARY

The Kansas population projections were prepared for the state's Legislative Educational Planning Committee to estimate future higher education enrollments. They are primarily targeted for research purposes because of limitations regarding the use of 1980 Census data.

Both state and county projections were developed by using the cohort-survival method, the standard demographic technique, which combines the effects of mortality, fertility and migration to project changes in the age composition of the future population. Current data were available for deaths and births and their predicted future change. In the absence of more recent data, the historic migration rates (1975-80) published by the U.S. Census Bureau provided the basis for developing migration rates for the projection which have been adjusted by the 1987 Census population estimates to incorporate more recent trends in statewide migration patterns. Since the projections are based on historic (1980 Census) data and represent an extrapolation of current trends in migration, they should not be viewed as immutable or as an exact forecast, but should be regarded as broad indicators of future population levels. In particular, the projections for counties with a major higher educational facility or military institution should be treated with great caution and are considered less reliable. This is attributable to difficulties in tracing the actual migration patterns of the student and military population every census decade.

Among the most important features of the projections are: (1) the slowdown in growth of the state's population (see Table 7 and Figure 2), (2) the persistence of an overaged population into the future, (3) the relative decline in the youngest and young-adult age cohorts, and (4) the great regional disparity in population growth between fast growing and declining counties (see Figure 4).

Despite decades of outmigration, birth rates in Kansas will be high enough to sustain slow overall growth of the state's population over the next three decades, which will continue to be about half (1980-1990) or two third (1990-2020) below the national average.

TABLE A: KANSAS AND U.S. POPULATION, 1960-2020

	<u>Total KS</u>	<u>Change KS</u>	<u>Change US</u>	<u>Kansas/U.S. Ratio</u>
1960	2,178,611	14.34%	19.00%	1.21
1970	2,249,071	3.23%	13.32%	1.10
1980	2,363,679	5.10%	11.48%	1.04
1990 (Proj.)	2,496,862	5.63%	10.20%	1.00
2000 (Proj.)	2,600,636	4.16%	7.33%	.97
2010 (Proj.)	2,698,976	3.78%	5.70%	.95
2020 (Proj.)	2,779,681	2.99%	4.72%	.93

Source: Summarized from Table 7.

An important observation to be made from the projections is the shrinking proportions of the youngest and young-adult age groups with respect to total state population (Figure 3), a fact that will impact the availability of labor in the future. Another significant observation is the existence of an overaged population in Kansas, which will increase its proportion of total population in the future and will reach its peak in 2020 when the baby-boom generation enters the older age cohorts (Figure 3 and Table 8). The increasing proportion of the population 65 and over and the decrease in the young age cohorts are reflected in the rise of the median age from 30.1 in 1980 to 35.9 in 2000 (Table 10).

Regarding the regional imbalance in future population growth in Kansas, shrinking or growing population is largely influenced by economic determinants. As Figure 4 indicates, most counties with declining population between 1980 and 2000 are concentrated in the rural northwest, northcentral, southcentral and southeast part of the state, where the county economies are based on agriculture or the oil industry. All metropolitan counties, except for Wyandotte County, are projected to experience significant population growth through the year 2000 and beyond.

## 1. INTRODUCTION

This report provides population projections by age and sex cohorts for the state of Kansas and its 105 counties at five-year time intervals up to the year 2020. The projections are based on 1980 Census counts, the latest detailed and reliable population data available. Thus, the 1985 population breakdown in the projection tables is already a forecast based on 1980 population. National mortality rates and fertility and migration trends in Kansas are used as projection parameters.

Being eight years away from the latest census, 1988 is not a good year for undertaking population projections. The base population used for the projection (1980 census counts), will have changed considerably in size and age composition. Also, the more recent trends in migration patterns of the various age-cohorts may not be fully reflected in the projection, owing to the lack of more recent detailed migration data. Therefore, the Kansas population projections should only be used as broad indicators for future population levels, and not as an exact forecasts.

The report's first section discusses the forecasting variables and assumptions underlying these projections. Population projections are mathematical extrapolations of historical and current trends to predict future population levels that will exist if the assumptions embodied in the projection model prove to be valid in the future. The projected population is therefore a result of several predicted factors (i.e. assumptions about migration, fertility and mortality trends) rather than a prediction itself. Population projections are correct if the base population (1980 Census data) and the forecasting variables (especially migration rates) are correct and if the underlying assumptions turn out to be correct. An evaluation of the assumptions

is therefore of importance in assessing the value and reliability of the projection.

The second section deals with the projection technique and the explicit projection equations employed to calculate future population. The final section gives the projected population by age and sex breakdown for all 105 Kansas counties and the state. The state projections are published with a high, medium and low series based on different assumptions about migration (see section 5).

## 2. METHODOLOGY AND FORECASTING VARIABLES

The population projections presented in this report are based on three forecasting variables: mortality, fertility and migration. An assessment of the likelihood of future changes in these trends, especially the migration trend, is given in the next section.

The cohort-survival method was used to project the state and county population by sex and five-year age cohorts. This approach combines the effects of mortality, fertility and migration so as to project changes in the age composition of the future population. More precisely, the method proceeds by surviving five-year age cohorts for each five-year period into the next higher age groups by adding births, deducting deaths and adjusting for migration. As an example, the number of persons in the age-cohort 20-24 in a county in 1985 would be equal to the number of persons aged 15-19 in 1980 minus the number of deaths in that specific age group plus the net difference (net migration) between those who moved into the county and those who outmigrated between 1980 and 1985. The number of persons in the 0-4 age-cohort at the end of each projection period was calculated by applying six age-specific birth rates to the six female cohorts that were in their childbearing years (15 to 44 years) during the projection period examined, again adjusting for survival and migration.

As has been already indicated, the cohort-survival method requires assumptions on migration, fertility and mortality, in addition to the number of people in each age-cohort for the initial base population (1980 in our case). Obviously, the result of the projections depends entirely on the assumptions made and on the initial base population used.

### 3. MIGRATION, FERTILITY AND MORTALITY ASSUMPTIONS

Migration assumptions are the most critical factor in population projections. Migration is a demographic factor that responds quickly to economic change, so it is much harder to predict than fertility and mortality trends. Although the general assumption is made that there will be no profound turnaround in the state's economic and demographic situation, there can be unforeseeable changes in trends at the state or county level that could drastically affect migration patterns and alter population size and composition.

Some of these changes could be minor, but others such as industries entering or leaving an area, the closing down of a railroad system, a major construction project, or a recovery of the oil industry could cause significant changes in county population. Such changes cannot be predicted and cannot be incorporated into the projection model. For example, in the 1970s it was impossible to predict the population growth in Finney and Ford counties resulting from growth in the beef processing industry, which brought a high influx of Hispanics and Southeast Asians to these areas. Similarly, it could not be envisioned in the 1970s, that some counties (Barton, Greenwood, Ellis, Rice) would face population losses due to the decline of the oil industry. Thus, the projections in this report should not be considered immutable, but should be viewed as being dependent on unforeseeable future economic events.

The three forecasting variables underlying these projections and the specific assumptions about future fertility and migration trends are explained below.

#### 1. Death (Survival) Rates

The survival rates used for these projections are national rates and are

the most recent rates that have been published by the U.S. Bureau of the Census for use in their population projections. These rates were projected by the Census Bureau for five-year periods and for five-year age cohorts from 1980 to 2020 (see Table 1). It is assumed that the Kansas population will follow the pattern of increasing national survival rates.

## 2. Birth (Fertility) Rates

In order to project the 0-4 year-old age cohorts for each five-year period, age-specific fertility rates for the six female age-cohorts in the main childbearing age (15-44) were used (see section 4, projection equation (6)).

For the state projections, average fertility rates for each female cohort were derived from 1980 Kansas birth statistics, which were trended into the future using the national forecast on future birth rates for the U.S. (see Table 2A, medium series). The medium series assumes that the national fertility rate will continue to increase during the 1980s until it reaches 2.2 per woman in 1990, then remain at that level until 2010 when it begins to drop to its ultimate level of 2.1 children per woman.

Technically, Kansas future birth rates were obtained by calculating the ratios of actual Kansas birth rates by age group for 1980 to the national rates. These ratios (gap between state and national rates) were assumed to linearly approach 1.0 by the year 2020, i.e. Kansas birth rates will eventually reach the level of the lower national birth rates by 2020. The projected Kansas birth rates used in the population projections are shown in Table 2B.

For the county projections, future births could not be calculated with sufficient accuracy using the average Kansas fertility rates. As expected, rural and urban areas of the state differ significantly in their birth rates. Birth rates in rural counties lay well above the statewide average. Also, counties

with a high percentage of minority population such as Finney, Ford, Grant, Seward, and Wyandotte, showed significantly higher birth rates than the statewide average. Furthermore, counties with a high ratio of student and/or military population, caused problems in projecting future births using the average Kansas fertility rates. This is because the model originally produced a high number of children for the entire female student population, which does not correspond with the reality that the majority of female students postpone childbearing until after college. To correct the described regional or county-specific variations in fertility rates, the average Kansas birth rate table used in the state projection was adjusted for each county, based on their actual births in the five-year period between 1981 and 1985. Technically, this was accomplished by multiplying the average Kansas birth rates with the quotient of actual births occurring in each county between 1981 and 1985 to projected births at the average statewide fertility rates, with the survival of infants taken into account.

The only county not being assigned its specific fertility rates was Geary County, which showed a tremendous discrepancy between projected births at average state fertility rates (2,811) and actual births reported by the Department of Human Health and Environment between 1981 and 1985 (6,386). This is due to the military hospital's reporting procedure, which attributes all births occurring at the hospital to Geary County, no matter where the mother actually resides after giving birth.

### 3. Migration Rates

The key projection parameters that will affect Kansas future population profoundly are the migration rates. While changes in survival and birth rates are expected to be minor and have relatively small impacts on future population change in Kansas, migration will affect future population more profoundly. In the projection model, state and county-level net migration rates for each age and sex cohort have been used. Net migration is the difference between the gross outflow and inflow of people.

Eight years away from the latest census, the only detailed migration rates for all age and sex cohorts are the five-year rates for 1975-1980, published by the Bureau of the Census. These measured (counted) rates for the period 1975 to 1980 have been adjusted by using the latest estimates by the Census Bureau on total net migration for 1980-1987 by county. By adjusting the 1975-1980 rates with the new estimates on net migration, critical trend changes in county-level migration could be incorporated in the projection. The adjustment technique employed for these projections is described in the second section.

Besides getting reliable migration rates for the first projection period (1980-85), predicting future migration patterns is another problem in making population projections. Kansas and most of its counties have experienced a long history of outmigration (see Table 3). In the decade 1960-70, almost all age groups had remarkable rates of outmigration. Between 1970 and 1980, outmigration slowed, and it was restricted to the young and middle-aged population. (See Table 4.) However, we cannot simply expect these levels of outmigration to be maintained in the future. A continuation of past outmigration trends would result in a complete population loss in some rural Kansas counties. A continuation of past inmigration to urban and other areas would result in a pronounced population explosion of counties such as Johnson, Sedgwick, Finney,

Ford, or Coffey, some of which have only experienced a one-time temporary population increase (e.g. Coffey during the construction of the Wolf Creek Nuclear Power Plant).

Since a straight extrapolation of past migration trends is not an appropriate tool for projecting future population, the (adjusted) migration rates are assumed to approach zero linearly by the year 2020. Thus, one cannot clearly foresee future migration behavior of the Kansas population. In other words, it is assumed that migration levels off by the year 2020. This is a strong but reasonable assumption that has been applied to the state and the majority of all counties. However, for counties with a temporary high immigration, the above assumption had to be slightly modified. For Finney, Ford, Seward, and Kearny counties, migration was assumed to level off by 1990 as the beef processing industry becomes stabilized in the region. Likewise, Butler County's immigration decreased due to the decline of the oil industry and is assumed to level off by 1990. For Leavenworth County, which experienced immigration during the construction of KCI and is expected to continue to benefit from the economic development associated with the airport, migration was assumed to level off by 2000.

#### 4. Migration Rates for College and Military Population

Using the 1975-80 migration rates published by the Census Bureau and adjusting them with the Bureau's current estimates of gross county-level migration, it was impossible to obtain plausible results for counties with a high student or military population (over 10% of total population). This might be due to problems of tracing actual migration patterns of student and military population every census decade. For instance, part of the former student or military population might not report that they had lived in a college or military town because they did not consider it their permanent residence. Employing the adjusted migration rates, as for the majority of all counties, caused the projections of the college or military age groups (15-19 and 20-24 years) to decline unrealistically by the year 2020, even when migration rates were kept at a constant level throughout 2020 and not assumed to go to zero linearly. In view of the described difficulties, specific migration rates for counties with large student or military populations were calculated from the 1980 age distribution of the population and the 1985 population estimates by the Census Bureau. These migration rates were employed for 5 age-cohorts for "college-type counties" (Douglas, Riley, Crawford, Ellis, Lyon). For the "military-type counties" (Riley, Geary), it seemed necessary to include 7 age-cohorts since it was assumed that there is higher in- and outmigration of children and of military employees in the older age groups.

#### 4. PROJECTION EQUATIONS

The basic projection equation (1) was developed to project population totals for sixteen age groups and eight time intervals for males and females. The sixteen age groups are the five-year age cohorts from 5-9 to 80-85 years (see Table 5). Future migration rates are assumed to linearly approach zero by the year 2020 using equation (2). The equation to determine the current adjusted migration rates from the 1975-80 Census rates (3) distributes the 1980-87 total net migration (as estimated by the Census Bureau) proportionately to the 1975-80 migrants to each age cohort. Future births are estimated using equation (6) which takes the average number of females in two subsequent time intervals for the five childbearing age cohorts into account, adjusted for survival. To allow for a better estimate of the 85+ age group, the specific estimation equation (5) uses both, the 80-85 and 85+ age groups. The eight projected time periods are five years apart, beginning in 1985 and ending in 2020. The projected time periods can be interpolated to 40 one-year time periods.

Except for the 0-4 and 85+ age groups in each sex, the following basic equation is used to project a five-year age-sex group:

$$P_{j+1,t+1}^{(s)} = P_{j,t}^{(s)} \times SR_{j,t}^{(s)} \times (MR_{j,t}^{(s)} + 1) \quad (1)$$

where:  $P_{j,t}^{(s)}$  is the population of a five-year age cohort  $j$  in the year  $1980 + 5t$  ( $t=0, 1, 2, \dots, 7$ ),

$SR_{j,t}^{(s)}$  is the survival rate of a given five-year age cohort  $j$  in the five-year time period beginning in the year  $1980 + 5t$ ,

$MR_{j,t}^{(s)}$  is the five-year net migration rate of a five-year age cohort  $j$  during the five-year time period beginning in the year  $1980 + 5t$ ,

- (s) indicates sex, either male (m) or female (f)  
j is a five-year age cohort, ranging from 0 to 18 (see Table 5)  
t is a time index ranging from 0-7 (see Table 6).

While the survival rates  $SR_{j,t}$  are obtained from Census survival rates  
for the U.S. (see Table 1), future migration rates  $MR_{j,t}$  had to be  
computed assuming that the current rates for 1980-85 linearly approach 0 by  
the year 2020. The formula is:

$$MR_{j,t}^{(s)} = MR_j^{(s)} * \frac{7-t}{7} \quad (t=0,1,2,\dots,7) \quad (2)$$

The equation to determine the adjusted migration rates from 1975-80 Census  
migration counts is:

$$MR_j^{(s)} = \tilde{MR}_j^{(s)} * N * \tilde{MR}_j^{(s)} / T \quad (3)$$

where:  $MR_j^{(s)}$  are the 1975-80 migration rates based on census migration  
counts calculated through

$$\tilde{MR}_j^{(s)} = \frac{\tilde{M}_j}{P_{j-1}} = \frac{\tilde{M}_j \times SR_{j-1}}{P_j - \tilde{M}_j} \quad (4)$$

$N = (M * 5/7) - M$  measures the difference between the 1975-80 and the  
1980-85 crude net migration rates, i.e., the  
"increase" in net migration (which may be negative),

$\tilde{M}$  is the net migration from 1975 to 1980,

M is the Census estimate on net migration from 1980 to 1987 and

$$T = \sum_j |M^{(s)}| \text{ total movement of in- and outmigrants} .$$

The oldest age group, the number of people 85 and over, is estimated by combining the two oldest age cohorts from the previous period by the following equation:

$$\begin{aligned} P^{(s)}_{18,t+1} &= \left( P^{(s)}_{17,t} \times SR^{(s)}_{18,t} \times (MR^{(s)}_{18,t} + 1) \right) * \\ &\quad \left( P^{(s)}_{18,t} \times SR^{(s)}_{18,t} \times (MR^{(s)}_{18,t} + 1) \right). \end{aligned} \quad (5)$$

For the youngest age group (0-4), the population is derived from the estimated births during a given five-year period as follows:

$$P^{(s)}_{1,t+1} = B^{(s)}_{0,t} \times SR^{(s)}_{1,t} \times (MR^{(s)}_{1,t} + 1) \quad (6)$$

where: B is the estimated number of births in a five-year time period.

Births are estimated from the number of females in the childbearing years (15-44) as follows:

$$B^{(s)}_{0,t} = 5 \times \sum_{j=4}^9 \frac{\left( P^{(f)}_{j,t} + P^{(f)}_{j,t+1} \right) \times BR^{(f)}_{j,t+1}}{2} \times S^{(s)}_{0,t} \times SR^{(s)}_{0,t} \quad (6)$$

where: BR is the age-specific birth rate,

S is the proportion of male (0.51) and female (0.49) births,

SR is the survival rate of the 0-4 year-old age cohort.

## 5. FEATURES OF THE PROJECTIONS

As for the most part of this century, high birth rates in Kansas will continue to sustain slow population growth in the future (see Figure 1), despite the state's long history of outmigration. However, if the current trends in migration, mortality and fertility persist, the state's population is projected to further slow its path of growth over the next three decades. As can be seen from Figure 2, growth rates will be further declining and remain below the national average over the next 30 years, with the gap between the state's and national growth rates to further narrow.

**TABLE 7**

Figure 1  
KANSAS POPULATION TRENDS

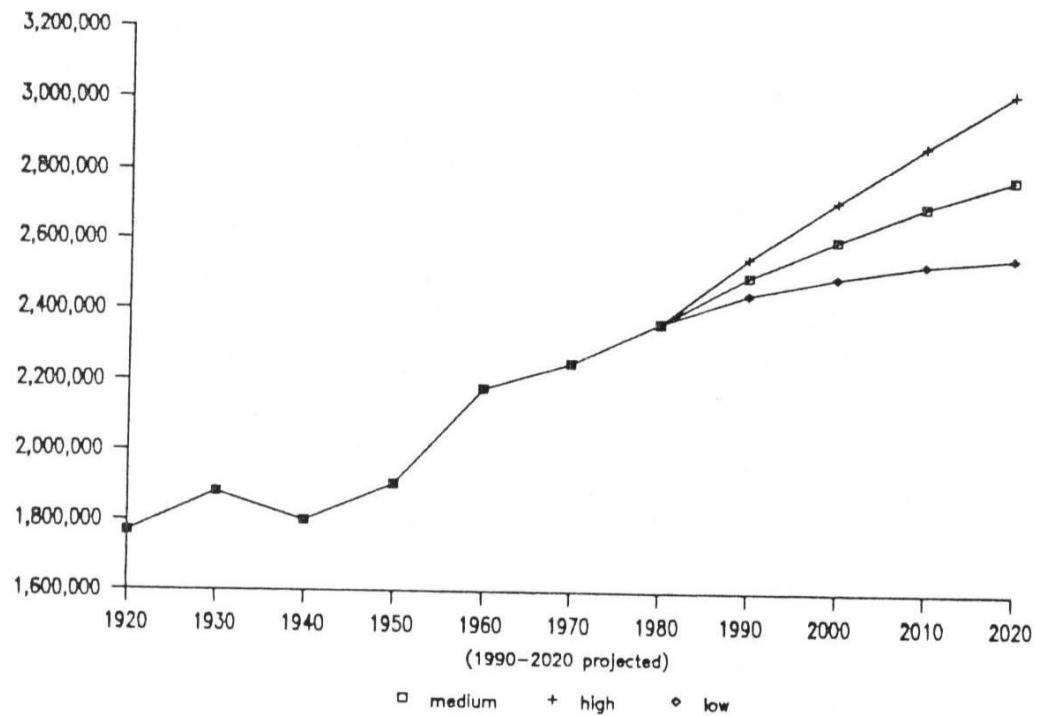

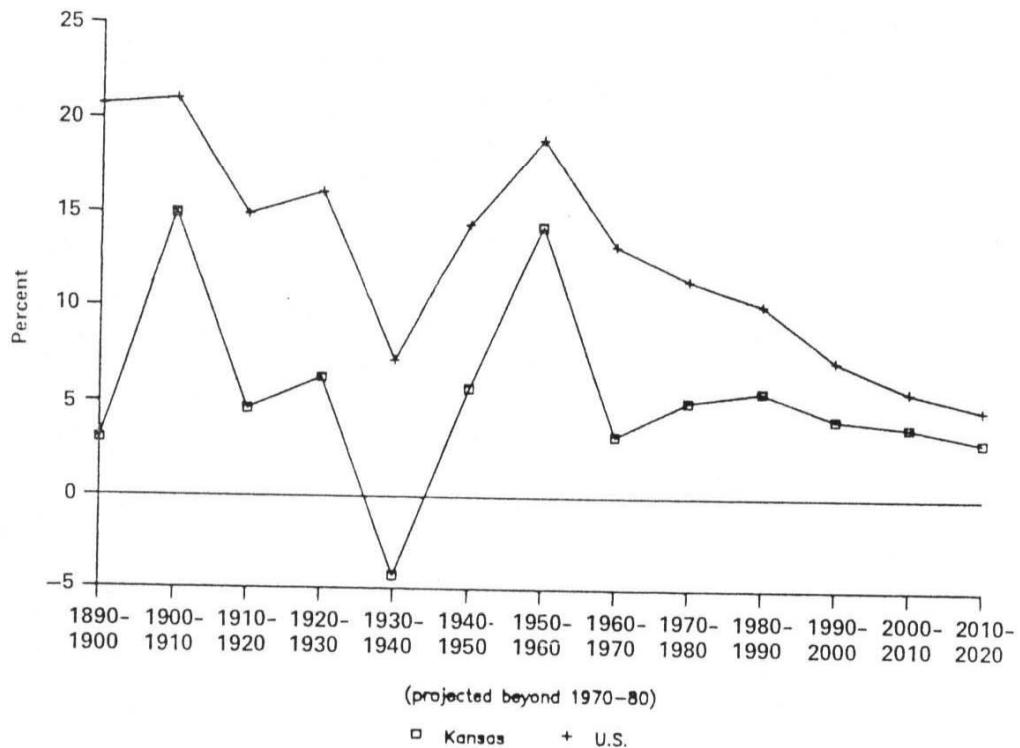

Figure 2  
KANSAS AND U.S. POPULATION GROWTH

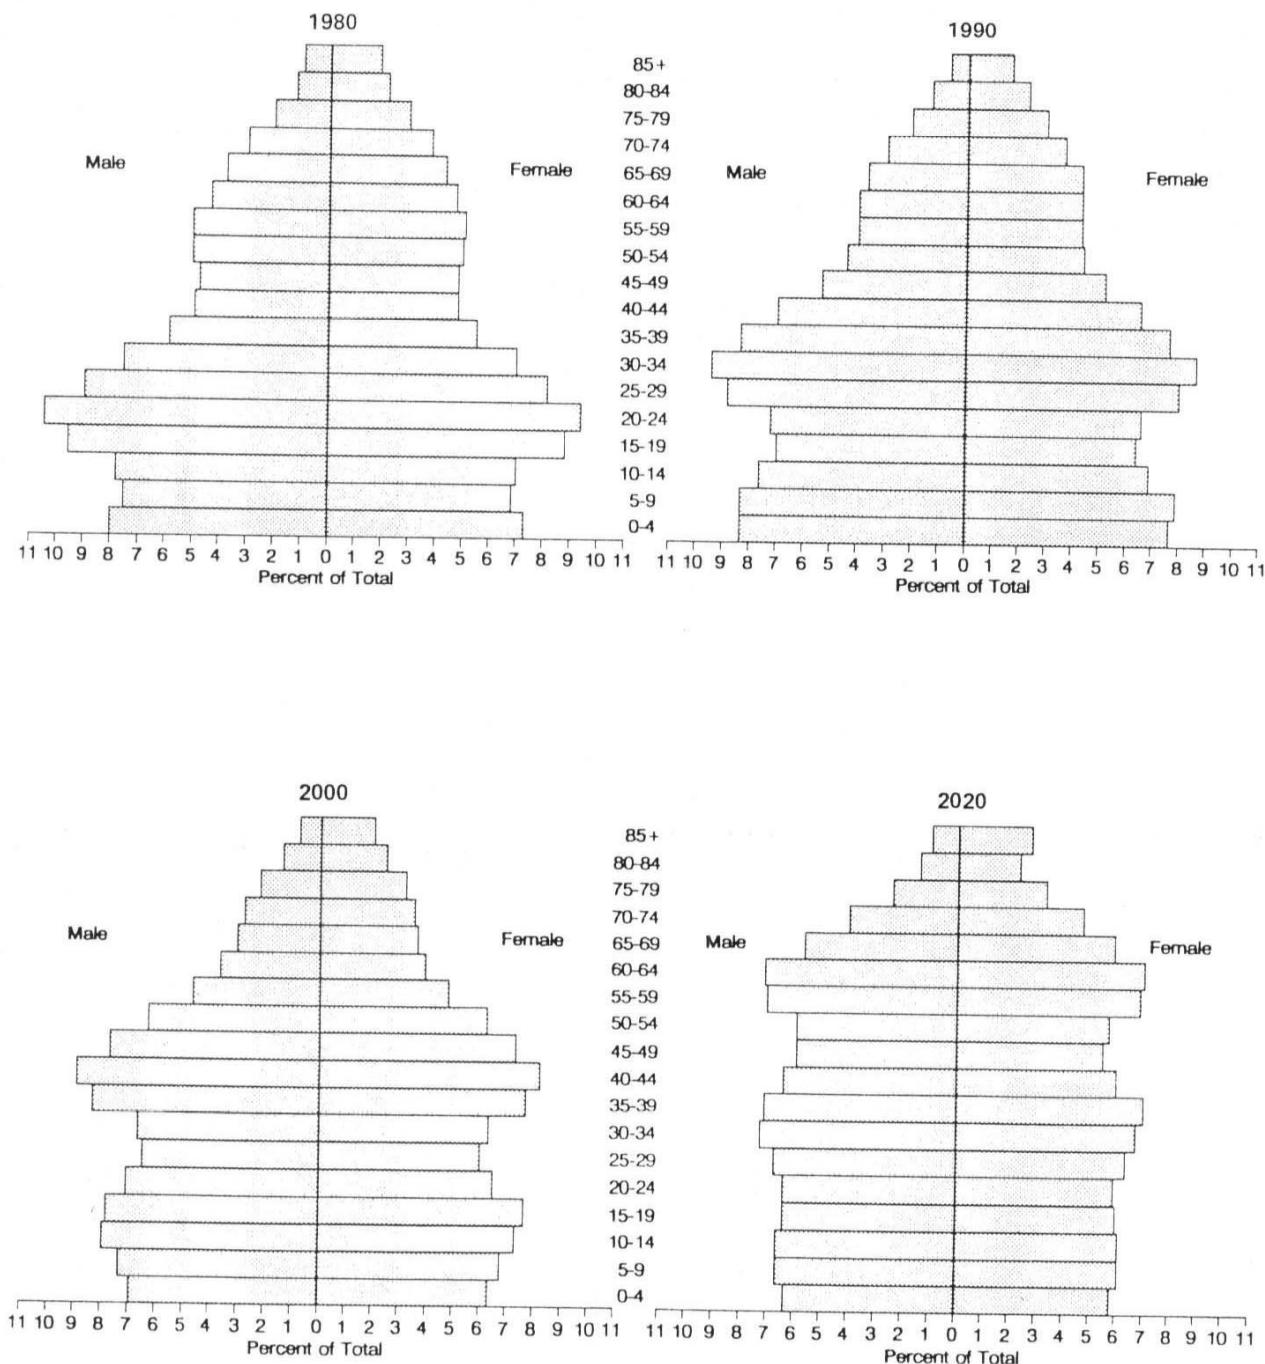

As Table 7 reveals, a 5.6% increase in total state population is projected for the decade 1980 to 1990, compared to 10.2% for the U.S. Between 1990 and 2000, the growth will slow to a 4.2% rate, nearly 3% below the national average of 7.3%. Beyond 2000, the state's population growth is projected to further slow and to reach about 3% for the period 2010 to 2020, when the U.S. population growth will decline to a 4.7% rate. Since the gap in population growth rates is projected to narrow, the ratio of Kansas to U.S. population will decrease more slowly over the next 30 years than has been the case for the past three decades (see Table 7). While this ratio was 1.36 in 1950 and 1.04 in 1980, it is projected to stabilize between 1.0 and .93 in the future.

Another observation to be made from the projections is the changing age structure of the population (see Figure 3 and Table 9). Because of high fertility, Kansas has a much younger age composition in 1980 than in 2020. Whereas the age composition in Kansas in the 1960s and 1970s had the shape of a pyramid as in today's less developed countries with high fertility rates, the future Kansas age structure will closely resemble a rectangle by 2020, which is typical for countries with a history of low birth rates such as most highly developed countries.

In the years ahead, the age structure in Kansas will continue to be influenced by the baby-boom generation, those persons born in the years 1946 through 1964. Figure 3 shows the progression of the baby-boom bulge through the population age structure and the shrinking of the younger age cohorts in the future, which will eventually lead to a stationary population.

The projected decline in the youngest and young adult age cohorts is already obvious in 1990. The years 1985 to 1990 mark the peak of the "baby boomlet", which started in the mid 1970s when the baby-boom generation started to have children. In line with the declining birth rates predicted by the U.S.

Figure 3  
AGE AND SEX STRUCTURE OF THE KANSAS POPULATION  
1980 - 2020

Census Bureau beyond 2000 for the nation as a whole and the smaller age cohorts following the baby-boom generation, the two youngest age cohorts (0-4 and 5-9 years) will decrease their share of total Kansas population from 8% in 1990 to 6.2% in 2020. Likewise, the three young adult age cohorts (15-19, 20-24 and 25-29 years) are projected to have a significant drop of their shares of total population beyond 2000 (see Table 9), a combined effect of lower birth rates and outmigration, which will affect the size of the future work force in Kansas.

Following a national trend is a steadily increasing proportion of the elderly population in Kansas (see Table 8). Unlike the U.S., Kansas has already faced the problems of an overaged population in previous decades when outmigration of young adults resulted in a higher proportion of the elderly. According to the projections, the proportion of the population 65 and over will grow from 13% in 1980 to 16.8% in 2020. The year 2020 will be the time when the baby-boom generation will enter the older age cohorts. A similar increase in the proportion of the elderly population can be observed for the nation as a whole (see Table 8). Beyond 2000, the proportion of the Kansas population 65 and over is projected to even slightly dip below the national average, a phenomenon attributable to the heavy outmigration of young people during the 1960s and 1970s.

Table 10 also mirrors the relative aging of the population. The median age is projected to rise from 30.1 in 1980 to 35.9 in 2000. According to the Kansas and U.S. projections, the median age in Kansas will fall below the national average beyond 1985.

The state's regional disparity in population distribution and population growth is obvious from Figure 4, which shows counties with increasing and declining population between 1980 and 2000. Corresponding to the regional economic imbalance within the state, most counties with declining future

population are concentrated in the northwest, northcentral and southeast part of the state. Most of them are based on agriculture or were hit by the oil crisis (e.g. Greenwood, Rice, Barton). As expected, Johnson County will be the fastest growing area in the state between 1980 and 2020 (60.4%), followed by Finney (53.1%) and Leavenworth (51.9%) counties. The high growth rates for the counties surrounding Finney County is attributable to the spillover of the immigrant workers attracted by the beef processing industry and to statistical aberration occurring to growth rates of a small population. Counties with moderate growth rates are Sedgwick/Butler (17%) and the Kansas City suburban metropolitan counties, such as Leavenworth (51.9%) and Miami (22%). Douglas County, ranking among the fastest metropolitan counties in the state if Johnson and Wyandotte counties' growth rates are averaged, is projected to have a 24.4% increase in population by 2000.

Figure 5  
KANSAS POPULATION IN 2000 (PROJECTED)

The map shows the state of Kansas divided into its 105 counties. Each county is outlined and contains its name and projected population for the year 2000. The counties are grouped into four major regions: North-Central, South-Central, Southeast, and Southwest.

Region	County	Population (2000)
North-Central	Cheyenne	3,319
	Sherman	6,411
	Wallace	1,971
	Greeley	2,000
	Hamilton	2,545
	Stanton	2,984

## 6. STATE AND COUNTY PROJECTION TABLES

Three sets of state projections are presented in the report based on three different assumptions about net migration trends: high, medium and low (see Table 14 and Figure 1). The medium series are based on adjusted Census migration rates (see sections 3 and 4). The high and low series are projected with migration rates that are 1% higher or lower than the actual net rates used for the medium series. Suppose, for example, the medium series migration rate for an age group was 20 per thousand, or 2%. The high series would be 3% or 30 per thousand, and the low series would be 1% or 10 per thousand. A comparison of Kansas population projections by the U.S. Census Bureau and by the Institute of Public Policy and Business Research is shown in Table 11.

TABLE 11  
KANSAS POPULATION PROJECTIONS COMPARED  
(MILLIONS)

	1985	1990	2000	2010	2020
U.S. Census Bureau Medium Series	<b>2.450</b>	<b>2.492</b>	<b>2.529</b>	<b>2.564</b>	NA
IPPBR: High Series	2.450	2.549	2.710	2.872	3.020
Medium Series	<b>2.424</b>	<b>2.497</b>	<b>2.600</b>	<b>2.699</b>	<b>2.799</b>
Low Series	2.399	2.445	2.494	2.534	2.555

The county projections are presented as medium series only. They are printed out by age group, but are available by sex breakdown on microcomputer diskettes. Because of the previously mentioned problems of tracing migration patterns of student and/or military population, the projections for counties with a high population dynamic due to a major higher education or military institution are less reliable than others and should be treated with greater caution than others. These counties are: Douglas, Riley, Geary, Crawford, Lyon and Ellis.
